PRELIMINARY AMENDMENT

Assistant Commissioner for Patents
Box Patent Application
Washington, D.C. 20231

Sir:

Please amend the above-identified application as follows:

IN THE CLAIMS:

Please cancel claims 5-15 and 20-30 without prejudice, and amend claims 4 and 19 as follows:

4. Apparatus according to claim 1, wherein the first termination point is associated with an audio or visual display apparatus, and is provided with means for detecting a ringing tone delivered to the first termination point, and means for generating a signal for transmission to the display apparatus in response to said ringing tone, in order to cause the display apparatus to display a call alert indication.

19. A method according to claim 16, wherein when ringing tone is delivered to the selected termination point, a signal is transmitted to an audio or visual display apparatus associated with the selected termination point, to cause the display apparatus to display a call alert indication.

Please add the following new claims 31-49 as follows:

--31. A method for forwarding incoming cellular communications to an aircraft, comprising:

receiving a request to divert incoming calls for a cellular telephone number to a communication system on board an aircraft;

associating a diversion instruction with the cellular telephone number, the diversion instruction representing an instruction to forward an incoming call for the cellular telephone number to the communications system aboard the aircraft; and

considering a state of a cellular telephone associated with the cellular telephone number as busy, regardless of an actual state of the cellular telephone;

wherein, an incoming telephone call to the cellular telephone number is forwarded, consistent with said considering and in accordance with the diversion instruction, to the communications system on board the aircraft.

32. The method of claim 31, wherein said associating a diversion instruction comprises giving priority to an address of the communications system on board the aircraft over any previous diversion instruction.

33. The method of claim 31, wherein the communication system on board the aircraft is a telephonic device aboard the aircraft.

34. The method of claim 31, wherein the communication system on board the aircraft is a communication device electrically coupled with a cellular telephone aboard the aircraft.

35. The method of claim 31, wherein the communication system on board the aircraft is a facsimile machine.

36. The method of claim 33, wherein the telephonic device is an aircraft telephone handset station.

37. The method of claim 31, wherein said associating a diversion instruction comprises modifying a preset diversion instruction associated with the cellular telephone to include the communication system on board the aircraft.

38. The method of claim 31, further comprising:
receiving an incoming call for the cellular telephone number; and
forwarding the incoming call to the communication system on board the aircraft.

39. The method of claim 31, the cellular telephone having at least one original diversion instruction prior to said associating a diversion instruction, the method further comprising:

- receiving an incoming call for the cellular telephone number;
- diverting, in response to an actual state of the cellular telephone being busy, the incoming call consistent with the at least one original diversion instruction.

40. A method for routing incoming cellular telephone traffic through a land-based host network to a cellular device user aboard an aircraft, the cellular device user having an associated cellular telephone number, comprising:

- receiving, at the host network, a request to register the presence of the cellular device user aboard the aircraft;
- the host network advising the cellular device user's home network that the cellular device user is within the operating jurisdiction of the host network;
- associating, at the host network, a primary divert on busy instruction with the cellular telephone number, the divert on busy instruction representing an instruction to divert an incoming call to a communication system on board the aircraft; and
- considering a current operational state associated with the cellular telephone number as busy, regardless of an actual operational state of the cellular device;
- wherein, upon receipt of an incoming call to the cellular telephone number, the host forwards an incoming call to the communication system on board the aircraft consistent with the primary divert on busy instruction.

41. The method of claim 40, wherein said associating a primary divert on busy instruction comprises giving an identifier of the communication system on board the aircraft priority over any preset divert on busy instruction.

42. The method of claim 40, wherein the communication system on board the aircraft is a telephonic device aboard the aircraft.

43. The method of claim 40, wherein the communication system on board the aircraft is a communication device electrically coupled with a cellular telephone aboard the aircraft.

44. The method of claim 40, wherein the communication system on board the aircraft is a facsimile machine.

45. The method of claim 42, wherein the telephonic device is an aircraft telephone handset station.

46. The method of claim 40, wherein said associating the primary divert on busy instruction comprises modifying preset diversion instructions associated with the cellular telephone to include the communication system on board the aircraft.

47. The method of claim 40, further comprising:

receiving an incoming call for the cellular telephone number; and

forwarding the incoming call to the communication system on board the aircraft.

48. The method of claim 40, the cellular telephone having at least one original divert on busy instruction prior to said associating a primary divert on busy instruction, the method further comprising:

receiving an incoming call for the cellular telephone number; and

diverting, in response to an actual state of the cellular telephone being busy, the incoming call consistent with the at least one original divert on busy instruction.

49. A method for receiving aboard an aircraft incoming calls for a cellular device user aboard the aircraft, comprising:

receiving, at a telephonic device aboard the aircraft, user data associated with a cellular telephone account having an associated cellular telephone number; and

sending, from the aircraft, at least the user data and seat data identifying said telephone interface;

wherein information sent from the aircraft in said sending represents a request to redirect an incoming call for the cellular telephone number to the telephonic device.--

ALLAWAY et al.

REMARKS

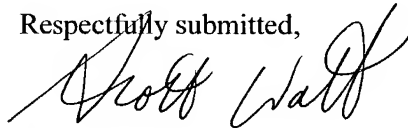

The present amendment removes multiple dependencies in the claims and adds new claims that further define that which Applicants regard as their invention. No new matter has been added.

The new claims herein are not responsive to prior art, and no estoppel should attach thereto.

In view of the foregoing, early action on the merits is respectfully requested.

Attached hereto is a marked-up version of the changes made to the claims by the current amendment. The attached page is captioned **"Version with markings to show changes made."**

Respectfully submitted,

Scott D. Watkins

VERSION WITH MARKINGS TO SHOW CHANGES MADE

Claims 5-15 and 20-30 have been cancelled and claims 31-49 have been added.

Claims 4 and 19 have been amended as follows:

4. Apparatus according to [any preceding] claim 1, wherein the first termination point is associated with an audio or visual display apparatus, and is provided with means for detecting a ringing tone delivered to the first termination point, and means for generating a signal for transmission to the display apparatus in response to said ringing tone, in order to cause the display apparatus to display a call alert indication.

19. A method according to [any of claims 16, 17 or 18] claim 16, wherein when ringing tone is delivered to the selected termination point, a signal is transmitted to an audio or visual display apparatus associated with the selected termination point, to cause the display apparatus to display a call alert indication.

PRELIMINARY AMENDMENT

Assistant Commissioner for Patents
Box Patent Application
Washington, D.C. 20231

Sir:

Please amend the above-identified application as follows:

IN THE CLAIMS:

Please add new claims 50-68 as follows:

---50. A method of registering to divert a telephone call to a telecommunications device on-board a vehicle, the method comprising:

receiving first and second identification information, the first identification information being associated with a cellular device, the second identification information being associated with the telecommunications device;
associating modified divert on busy instructions with the cellular device that identify the telecommunications device as a divert on busy instruction; and

setting an indication of a status of the cellular device as busy regardless of an actual status of the cellular device.

51. The method of claim 50 further comprising the steps of:
receiving a telephonic call intended for the cellular device;
diverting the telephonic call to the on-board telecommunications device consistent with the primary divert on busy instruction.

52. The method of claim 50 wherein the on-board telecommunications device includes a facsimile device.

53. The method of claim 50, wherein said associating comprises inserting a telecommunications device identifier as a primary divert on busy instruction within any existing divert on busy instructions.

54. The method of claim 50, wherein said receiving, associating and setting occur at a host network, the cellular device is associated with a home network different from the host network, and said method further comprising advising the home network that the cellular device is roaming within the coverage of the host network.

55. A method of registering to divert incoming cellular telephone calls to an on-board telecommunications device, the method comprising:
registering a cellular device as roaming on a host network regardless of the actual location of the cellular device relative to the host network; and
updating, in response to said registering, a primary divert-on-busy instruction of the cellular device as an on-board telecommunication device.

56. The method of claim 55, further comprising setting an indication of a status of the cellular device as busy regardless of an actual status of the cellular device.

57. The method of claim 55, wherein the cellular device is associated with a home network, said method further comprising advising the home network that the cellular device is roaming on the host network.

58. The method of claim 55 further comprising the steps of:
receiving a telephonic call placed to the cellular device; and
diverting the telephonic call to the on-board telecommunications device.

59. The method of claim 55 wherein the on-board telecommunications device includes a facsimile device.

60. A method of receiving a telephonic call placed to a mobile station at a telecommunications device on-board a vehicle comprising:
receiving a call forwarded from a home network, the call being placed to the mobile station;
returning a busy signal for the mobile station regardless of an actual state of the mobile station;
accessing a divert-on-busy instruction for the mobile station; and
forwarding the call to the vehicle consistent with said accessing;
wherein the call terminates at the telecommunications device on-board the vehicle.

61. The method of claim 60, wherein the on-board telecommunications device comprises a facsimile device.

62. The method of claim 60, further comprising setting an indication of a status of the mobile station as busy regardless of an actual status of the cellular device.

ALLAWAY et al.

Page 4

63. The method of claim 60, wherein the mobile station is associated with the home network, said method further comprising advising the home network that the cellular device is roaming on a host network.

64. A method of receiving a telephonic call placed to a cellular device at a telecommunications device on-board a vehicle comprising:

- receiving first and second identification information, the first identification information being associated with a cellular device, said second identification information being associated with the telecommunications device;

- associating modified divert on busy instructions with the cellular device that identifies the telecommunications device as a divert on busy option;

- setting an indication of a status of the cellular device as busy regardless of an actual status of the cellular device;

- receiving a call forwarded from a home network, the call being placed to the cellular device;

- accessing the modified divert on busy instructions for the cellular device;

and

- forwarding the call to the telecommunications device consistent with said accessing;

- wherein the call terminates at the telecommunications device on-board the vehicle.

65. The method of claim 64, wherein the on-board telecommunications device includes a facsimile device.

66. The method of claim 64, wherein the mobile station is associated with the home network, said method further comprising advising the home network that the cellular device is roaming on a host network.

67. The method of claim 64, wherein said associating comprises inserting a telecommunications device identifier as a primary divert on busy instruction within any existing divert on busy instructions.

68. The method of claim 64, said method further comprising routing, when said actual status of the cellular device is busy, the call consistent with the existing divert on busy instructions.---

ALLAWAY et al.

CALL DIVERSION SYSTEM

This invention relates to mobile telephony, and in particular to systems for use on board vehicles.

5 There has been considerable activity in recent years in proposals to allow the use of mobile telephones in environments where conventional cellular telephony base stations cannot provide coverage, in particular on board ships and aircraft. These vehicles frequently travel beyond the range of land-based cellular base stations, which typically have a range of the order of .1 to 10km.

There are a number of special difficulties to be addressed if a standard cellular telephone is to be used in an aircraft. Firstly, many cellular base stations have antennas arranged for maximum gain in the horizontal plane, so an airborne cellular telephone may not be able to obtain a signal from any base station, even when flying over land served by a cellular base station network. Even if the radio range of the base stations does extend as high as the normal flying height of aircraft, there are further problems. Frequency re-use patterns, which allow several base stations to use the same radio frequencies without interference, are designed on the assumption that a mobile unit served by one base station is not able to exchange radio signals with other base stations using the same frequency. This assumption ceases to be valid if a mobile unit is several thousand metres above the ground, since it may be in line-of-sight of a large number of base stations simultaneously. Moreover, although reliable handover of a mobile unit can be achieved from moving vehicles travelling at speeds of up to 200km/h, a typical passenger aircraft travels at speeds approaching 1000 km/h. Airlines also impose restrictions on the use of powerful radio signals on board, as a precaution against possible interference with the aircraft's electronic systems.

For truly global coverage, satellite telephones are available. However, these are expensive and much heavier than a cellular telephone. Both cellular telephones and satellite telephones also suffer from the screening effect of being inside a metal hulled vehicle. As with cellular telephones, the unrestricted use of a portable satellite

30 telephone within an aircraft may be prohibited.

A user without his own satellite telephone may use special facilities provided on board, such as the service provided to several airlines by the applicant company under the Registered Trade Mark "Skyphone". This uses onboard terminals

connected, through a satellite link between the aircraft and a satellite ground station, to the telephone network. Another system, TFTS (terrestrial flight telephony system, marketed as "Jetphone"), operates in a similar manner, but uses a direct link between the aircraft and the ground station, without a satellite link. Similar systems are provided on board ships. However payment for these services is generally at the point of use (or prepaid), and may be in a foreign currency. Calls made to the user's cellular telephone will not be successful unless the calls can be diverted to the telephone number of the onboard user terminal (which will generally not be known to the caller), and any special facilities offered by the user's cellular network will in general be unavailable. A user with his own cellular telephone account which, through "roaming" agreements between network operators, can be used in many different countries, would therefore prefer to continue to use his cellular telephone subscription when travelling within or between these countries on board an aircraft or other vehicle.

According to a first aspect of the invention there is provided apparatus for enabling a first termination point of a first telecommunications system to initiate call diversion instructions in the switching system of a second telecommunications system such that calls initially directed to a telephone apparatus usable with the second telecommunications system are diverted to a selected termination point in the first telecommunications system, the apparatus comprising means in the first telecommunications system for identifying the telephone apparatus from which calls are to be diverted and the selected termination point to which calls are to be diverted, and an interface means between the first telecommunications system and the switching system of the second telecommunications system, the interface means comprising:

means to indicate to the switching system that the telephone apparatus is in a specified operating condition, irrespective of the true operating condition of the telephone apparatus,

and means to generate an instruction to the switching system to divert calls, intended for the telephone apparatus, to the said selected termination point of the first telecommunications system when the telephone apparatus is indicated as being in the said predetermined operating condition.

A second aspect of the invention provides a first telecommunications system, arranged for interconnection with a second telecommunications system to allow calls initially directed to a telephone apparatus usable with the second telecommunications relating to the telephone apparatus, means for receiving associated identification
5 information relating to the selected termination point, means for transmitting the identification information to a network interface unit, means for receiving authentication data from the interface unit, and means for connecting calls to or from the selected termination point in response to said authentication data. In the preferred arrangement the first and second telecommunications systems are a
10 satellite telephone system and a cellular telephone system respectively, the identification information being a user identity associated with the telephone apparatus, and the network address of the selected termination point.

A third aspect provides a network interface unit for interconnecting a first telecommunications system with a second telecommunications system such that
15 calls directed to telephone apparatus configured for use with the second telecommunications system may be diverted to a selected termination point in the first telecommunications system, the interface unit comprising:

means for receiving data identifying a user and a first termination point in the first network,
20 means to indicate to the switching system of the second telecommunication system that a telephone terminal associated with the user is in a specified operating condition, irrespective of the true operating condition of the telephone terminal, and means to generate an instruction to the switching system of the second telecommunications system to divert calls directed to the telephone user to the said
25 selected termination point of the first telecommunications system when the telephone apparatus is indicated as being in the said predetermined operating condition.

The telecommunications termination points may, for example, be user terminals of a satellite telephone system. They may be provided with reading
30 apparatus for reading an information carrier encoded with the user's identity. Such apparatus is commonly used for telephone terminals to which the public have access to allow calls to be charged to a user's credit card account, or an account with the service provider, or to deduct value from a stored value on the card.

means to store the address of termination points in the first system, means to record changes to the said addresses transmitted to it from the first system, and means to modify the diversion instruction in the switching system when such a change takes place. Alternatively, the termination points may be arranged simply to repeat the set-up process, causing the mobile unit to be re-registered with the interface unit, (which will not be apparent to the switching system, as it will perceive the same "virtual" base site controller), and to transmit a new call divert instruction to the revised address of the termination point.

The invention also provides a method of initiating, from a first termination point of a first telecommunications system, call diversion instructions in the switching system of a second telecommunications system such that calls initially directed to a telephone apparatus usable with the second telecommunications system are diverted to a selected termination point in the first telecommunications system, the method comprising the steps of;

in the first telecommunications system, identifying the telephone apparatus from which calls are to be diverted and the selected termination point to which calls are to be diverted,

indicating to the switching system of the second telecommunications system that the telephone apparatus is in a specified operating condition, irrespective of the true operating condition of the telephone apparatus,

and generating an instruction to the switching system to divert calls, intended for the telephone apparatus, to the said selected termination point of the first telecommunications system when the telephone apparatus is indicated as being in the said predetermined operating condition.

This aspect of the invention comprises several separate processes, some of which comprise further aspects of the invention. These processes interact to allow calls made to the telephone apparatus to be routed to the selected termination point.

The first part of the process is carried out, in the described embodiments, by a card reading device or similar apparatus associated with an onboard telephone termination point, which reads an information carrier encoded with the user's identity. The information carrier may be the part of a cellular telephone containing the user identity.

The second part of the process is a method according to a further aspect of the invention, for interconnecting a first telecommunications system with a second telecommunications system to allow calls initially directed to a telephone apparatus usable with the second telecommunications system to be diverted to a selected

- 5 termination point in the first telecommunications system, comprising the steps of;
receiving, from a first termination point, identification information relating to the telephone apparatus,
receiving associated identification information from the first termination point,
transmitting the identification information to the second network,
10 receiving authentication data from the second network, and
connecting calls to or from the selected termination point in response to said authentication data.

This process is, in the described embodiments, carried out by the ground-based systems of the satellite telephone network.

- 15 The third part of the process is a method according to a further aspect of the invention, for interconnecting a first telecommunications system with a second telecommunications system such that calls directed to telephone apparatus configured for use with the second telecommunications system may be diverted to a selected termination point in the first telecommunications system, comprising the
20 steps of:

- generating an instruction to the switching system of the second telecommunications system to divert calls directed to the telephone apparatus to the said selected termination point of the first telecommunications system when the telephone apparatus is indicated as being in the said predetermined operating
25 condition

- receiving data identifying a user and a termination point in the first network,
indicating to the switching system of the second telecommunication system that a telephone terminal associated with the user is in a specified operating condition, irrespective of the true operating condition of the telephone terminal,
30 generating an instruction to the switching system of the second telecommunications system to divert calls directed to the telephone user to the said selected termination point of the first telecommunications system when the telephone apparatus is indicated as being in the said predetermined operating condition.

However, standard on-board satellite telephone card readers may not be compatible with GSM "SIMs", or complete telephones. To avoid the need to modify the user terminals, a user identity may be carried on a special carrier compatible with the existing card readers. This user identity may be the user's cellular radio network identity (IMSI), or some other identity from which it can be derived.

In practice, the user identity required by the network (known in the GSM standard as the IMSI) is unique to one carrier (the "SIM") and is not encoded on any other. This provision is primarily a fraud prevention measure, made to prevent the user identity being used to access a cellular network when the authorised user is actually elsewhere. The invention also requires access to a cellular network when the user is actually not directly connected to that network but is elsewhere, but is communicating through the first telecommunications system. It is therefore necessary for the interface means ("Virtual" Base Site Controller) to obtain the user identity.

Embodiments of the invention will now be described with reference to the Figures, in which:

Figure 1 is a schematic diagram showing the functional relationships
20 between the systems which co-operate to form one embodiment of the invention

Figure 2 is a more detailed schematic diagram of the network termination and associated card reading equipment, which for illustrative purposes will be assumed to be on board an aircraft

Figure 3 is a diagram showing part of an alternative arrangement of network
25 termination, arranged for co-operation with a cellular telephone handset

Figure 4 is a schematic diagram showing the functional relationships between the components of the fixed part of the first telecommunications system which co-operate in the invention,

Figure 5 is a schematic diagram of the switching system, interface unit, and
30 associated parts of the second telecommunications system;

Figure 6 is a flow chart showing the process by which a diversion is set up in the second network to a termination connected to the first network

Figure 7 is a flow chart showing the process by which a call coming in to the second network is connected to a telephone connected to the first network

Figure 8 is a flow chart showing the process by which the second network restores the original settings for a telephone when it disconnects from the first
5 network.

Figure 9 illustrates the forwarding process implemented to a data message.

Figure 10 illustrates a conditional forwarding process for a data message.

Figure 11 is a flow chart showing a call diversion process, for use when the system has to be temporarily shut down.

10 The following embodiments illustrate the invention using a standard switched cellular network. However, the invention is applicable to other cellular networks, such as packet networks used to carry data over a distributed computer network such as the "Internet", carrying messages using formats such as the "Internet Protocol" (IP). Thus, unless the context clearly demands otherwise, any reference in this
15 specification to switching includes the equivalent routing functions in a packet network of this kind.

Figure 1 shows the general arrangement of the various components which co-operate in this embodiment. Note that traffic links (which can carry speech, data, etc) are shown as full lines, signalling links used only for call set up are shown as
20 broken lines.

The onboard part 2 (shown in more detail in Figure 2) comprises one or more handsets 25 (which, in the alternative arrangement of Figure 3, are the users' own cellular telephone handsets 31), connected to a termination point 20 of the satellite network. The termination point 20 is in communication with a ground station 4,
25 shown in more detail in Figure 4. In this embodiment, the communication link is made through an earth-orbiting satellite 6.

The principal components of the ground station 4 relevant to this invention are an antenna 44 which communicates, by way of the satellite 6, with the onboard system 2, an Access Control and Signalling Equipment (ACSE) 40 which carries out
30 call switching functions to allow calls to be placed through the public switched telephone network (PSTN) 8 to other telephones 85, and a Card Management System 42 which authorises the use of an individual terminal 25 according to user identities entered with respect to that terminal. There is also a register 43 of card identities, to

In those cellular systems where the user identity is carried on a data carrier card transferable between telephone handsets, the reading apparatus may be arranged to read this carrier. In the "GSM" standard these cards are known as "Subscriber Identity Modules" or SIMs, and are either of standard credit card size
5 (86mm x 54 mm) or rather smaller (14mm x 25mm), and may be transferred from one cellular telephone handset to another to allow the same telephone user account and directory number to be used with different handsets.

Another embodiment allows the onboard user terminal to co-operate with the complete cellular telephone. Although this requires a more complex interface between
10 the cellular telephone and the user terminal, it allows the user to use the functionality of his own telephone, rather than having to familiarise himself with that of an unfamiliar satellite user terminal.

However, as standard on-board satellite telephone card readers may not be compatible with GSM "SIMs", or complete telephones, the user identity, or a code
15 allowing its retrieval, may be carried on a special carrier compatible with the card reader to be used, and supplied to users wishing to make use of the facility.

In a further variant, falling within the scope of the invention, the user may gain authorisation for use of the system by entering a predetermined identification code using the user terminal, for transmission to the interface unit which then
20 retrieves the user identity and establishes the diversion process as already discussed.

In the cellular telephone system of the preferred embodiment the interface unit is arranged to appear to the switching system as if it is a typical radio base station control system, to which the mobile handset is currently working, although in fact no radio base stations are actually controlled by it. This will be referred to as a "Virtual"
25 Base Site Controller. The switching system itself requires no modification: it merely registers that the user is working to the "Virtual" Base Site Controller and stores the user details in its "Visitor Location Register" (VLR) as it would for a mobile unit working to any real base site controller to which it is connected. The interface unit also generates a call diversion instruction, which will appear to the switching system
30 to have come from the mobile handset, by way of the "Virtual" Base Site Controller. This call diversion instruction is set up in the switching system such that if the "Virtual" Base Site Controller responds to a call request directed to the mobile unit with a "busy line" response (or some other specified condition), calls are to be

diverted, through normal network interconnects, to a specified directory number, namely that of the satellite termination point to which the user is connected. The interface unit does not in fact monitor the real condition of the user terminal, (which is switched off or operatively connected to the satellite network termination point by a non-radio link), but instead always returns the "line busy" signal to the switching system.

Preferably, the interface includes a store to record any diversion settings existing for the telephone apparatus prior to the diversion to the second network being set up. This allows these settings to be retrieved when the user disconnects from the first telecommunications system, so that they can be reinstated in the switching system of the second telecommunications system or transferred to a further telecommunications system if the telephone apparatus makes contact with a real radio base station, thereby initiating a handover procedure from the "Virtual" Base Site Controller to the real one.

Should a second call attempt be made, the switching system may be arranged to divert it to a predetermined number such as the user's voice mail. The interface unit may be arranged to transmit a message to the termination point to indicate that such a voice mail message has been sent.

Some cellular telephones also have additional capabilities, such as for receiving facsimile messages, or for connection by way of a modem to a computer. A mobile user may have several network identities, all linked to the same SIM, for controlling different cellular termination devices having different capabilities. The standard at-seat satellite telephone terminal provided in aircraft is not equipped to receive such calls. However, the vehicle on which the terminal is fitted may be provided with a suitable terminal. Accordingly, the selected termination point to which calls are directed may be a termination point other than the first termination point from which the process was initiated. Where such is the case, the interface unit may be arranged to transmit a message to the first termination point to indicate that such a message has been sent to the selected termination point.

If the user termination is in an aircraft or other vehicle connected to a ground station (by satellite or otherwise), it may move from the area covered by one satellite (or ground station) to that of another. In that case, the network address of the termination changes. To accommodate this, the interface may be provided with

The user handset 25 provides the usual keypad, microphone and earphone to allow the user to make telephone calls. The user handset 25 and the card reader 23 are both connected to a processor 26 which converts data read from the card 24, and keystrokes input from the handset 25, into data signals for transmission over the radio link 29. It also provides identification data indicative of which of the terminals 21 it is. A further processor 27 performs analogue/digital conversion of speech signals from the handset 25.

Instead of the terminals 25, an alternative arrangement may be used as shown in Figure 3. In this arrangement each onboard terminal 25 is replaced by an onboard interface device 311 to which a user's own mobile radio telephone 31 can be connected electrically, thereby allowing the mobile telephone to be used without using its radio antenna. It is a modification of the system described in the applicant's company's International Patent Application WO97/36442, published on 2nd October 1997, to which the reader is referred for further details. In this modified version a GSM (Global System for Mobile communication) mobile telephone 31 comprises r.f. transceiver circuitry 32 coupled to an antenna 33, base band signal processing and control circuitry 34, a rechargeable battery pack 35, a switch 36 and a socket 37. The processing and control circuitry 34 has a data output terminal 34a coupled to both the r.f. transceiver circuitry 32 and a first contact 37a of the socket 37. A data input terminal 34b of the processing and control circuitry 34 is coupled to the r.f. circuitry 32 and a second contact 37b of the socket 37. A third contact 37c of the

socket 37 is coupled to a control input of the processing and control circuitry 34. Fourth and fifth contacts 37d, 37e of the socket 37, which are respectively for 0V and +V power supply lines, power the telephone 31, and may also be arranged to recharge its batteries 35. The +V terminal of the battery pack 35 is also connected
5 to the processing and control circuitry 34 and to an input terminal of the switch 36. The output terminal of the switch 36 is coupled to a +V input terminal of the r.f. circuitry 32. A control terminal of the switch 36 is coupled to an output of the processing and control circuitry 34.

The interface unit 311 comprises a control circuit 312, a user input unit 313,
10 including a keypad and a display, a V.24 33.6 kbit/s modem 314, a power supply unit 315 and a plug 316. The plug 316 has five contacts 316a-316e which correspond to contacts 37a-7e of the socket 37 of the mobile telephone 31. The first contact 316a of the plug 316 is coupled to a data input terminal of the control circuit 312 and the second contact 316b of the plug 316 is coupled to a data output
15 terminal of the control circuit 312. A bi-directional serial link 318 is provided between the control circuit 312 and the modem 314 for modem control and data signals. The third contact 316c and fifth contact 316e of the plug 316 are coupled to the +V output of the power supply unit 315. The fourth contact 316d of the plug 316 is coupled to the interface unit's 0V supply wiring. The user input unit 313 is
20 coupled to the control circuit 312 for the input of user commands and the output of display control signals from the control unit 312 to the user input unit 313. The +V output of the power supply unit 315 is also coupled to +V input terminals 312a, 313a, 314a of the control circuit 312, the user input unit 313 and the modem 314. The modem 314 is coupled to a telephone line 317 and the power supply unit 315 is
25 arranged to receive power from an electricity supply 319.

When the user wishes to connect to the interface unit 311, he connects the plug 316 of the interface unit 311 to the socket 37 on his telephone 31 by a cable (not shown). The voltage on the third contact 37c of the socket 37 is detected by the processing and control circuitry 34 which thereby determines that the telephone
30 31 has been connected to the interface unit 311. The connection of the battery 35 to the power supply 315 by way of the connections 37d/316d and 37e/316e also allows the battery to be recharged.

Once the processing and control circuitry 34 has determined that the telephone 31 has been connected to the interface unit 311, it sends a control signal to the switch 36, causing it to open, isolating the r.f. circuitry 32 from the battery pack 35 and the power supply 315 in the interface unit 311. The processing and control circuitry 34 also responds to the voltage on the third contact 37c of the socket 37 by selecting alternative control programs or constant data to allow for delays in the signal path from the telephone 31 to the controller 30 which are caused by the use of the satellite link 6 and the modems 314, 32.

In this arrangement, instead of the need for a separate card reader 23, the telephone 31 identifies itself to the telephone network 40/42 by generating its terminal identity code (IMSI in the case of a GSM telephone). The registration signal is not transmitted from the antenna 3 because the r.f. circuitry 32 is disabled. Instead, it is output to the interface unit 311 via the first contacts 37a, 316a of the socket 37 and plug 316

The operation of this onboard system will now be described with reference to Figure 6. When the card reader 23 or interface unit 311 detects the presence of a card 24 or handset 31 respectively, (step 601) it generates a prompt to indicate to the user that he may wish to have calls diverted to the onboard system. If the user requires this service, he enters a code on the keypad of the handset 25, 31 which causes a divert request to be generated (step 602). The details from the card 23 (or SIM of the handset 31) are then passed to the processor 26 which also provides the identity of the terminal 21 (step 603) and transmits the data to the interface unit 28.

Alternatively, these steps (602, 603) may be activated by the user without a card, by dialling an access code (divert request 602) followed by further keystrokes to identify the account to be used (terminal identity step 603). These keystrokes may include the user's MSISDN (which, as his own directory number would be known to him). To prevent misuse of the system by unauthorised personnel, a security code (Personal Identification Number: "PIN") may be added. This code may have been issued previously to the user, or the user may request such a code by making a call using the satellite system to his home network's customer service department and providing personal details to the operator to prove his identity.

The user may select for the identity of a terminal 21a other than his own at seat terminal 21 to be selected as the destination for incoming calls. For example, if

The conventional ground station equipment just described is augmented in the present embodiment by an interface 46 with the Home Location Register 73 of each network 7 whose subscribers are to be given access to the service. The

interface 46 which stores a concordance between the card identities and the card-holder's cellular radio telephone number (MSISDN: mobile systems integrated services data network number), on request from the data acquisition unit 42, which is arranged to recognise the card identities which require such translation. In a preferred
5 embodiment the concordance is supplied to a register 43 in the ground station by the operator of user's home network 7, when the network operator provides the user with the card. The operator of the home network 7 also records the concordance in its own Home Location Register 73. This arrangement allows the existing card readers 23 to be used on board the aircraft, without modification. If the users' mobile
10 subscriber identities are supplied from the onboard system, either by reading the identity (reader 311) or by the user keying it in, the store 43 can be used for verification, or omitted. Billing information is also returned to the user's home network 7.

The operation of the ground station will now be described with reference to
15 Figure 6. The data acquisition unit 47 receives the card details from the reader 23 (see steps 601 to 604 already discussed) and if it identifies as those details as corresponding to a cellular user (step 605), it retrieves the cellular user identity from the store 43 containing this concordance, or from the HLR 73 of the user's home network, (step 606). (This step can be omitted if the user's mobile network identity
20 is provided by the onboard apparatus 20).

The data transmission unit 46 then generates a signal for transmission of the cellular user identity, together with the identity of the terminal 21, to the cellular network 5 acting as host to the interface (step 607). This host network 5 will, in general, not be the same as the user's home network 7. The further steps (608 to
25 615) in this process will be described later, with reference to Figure 5.

If a cancellation signal is received from the aircraft in respect of a given terminal 21, (step 801, previously discussed) the data transmission unit 46 transmits a "cancellation" signal to the host network 5. As already discussed, the cancellation signal may be generated either for an individual handset 21, by its user dialling a
30 special code, or for all handsets as the result signals received by the radio interface unit 28 over the aircraft's data bus 22 indicative of the imminent end of the flight.

An embodiment of the host network 5 of the invention is shown in Figure 5. Its operation will be discussed with reference to Figures 6, 7 and 8 In this network 5

an interface unit 52 is provided, which is arranged to appear to the switching system 50 as if it is a normal base station of the cellular radio system.

In order to do this, the interface unit 52 is provided with a data acquisition unit 54 which receives from the card management system 42 of the ground station 4 the identity of the cellular telephone it is to represent, and the AES identity of the onboard terminal 20 (step 608, Figure 6). Mobile telephones have three identification codes: the equipment identity (IMEI, which will not be discussed further here), the directory number (MSISDN) and the actual SIM identity (IMSI). In practice, for security reasons, the IMSI is not made generally known, and a user is normally identified by his MSISDN unless the SIM itself is used. If the SIM is used in the card reader 23, or the user's telephone is used in the arrangement of Figure 3, (in which case no concordance is required) the IMSI can be read directly from the data received by the data acquisition unit 54. However, if the user keys in his own identification data (step 603), or a concordance is provided by the card reader 23, the data acquisition unit will receive the MSISDN, and not the IMSI. (There may also be a PIN or other security code, which is checked by the data acquisition unit 54).

In the GSM standard it is possible to obtain an IMSI if the MSISDN is known by interrogating the appropriate Home Location Register 73. To do this, the interface unit 52 transmits a "request for routing information" signal, using the MSISDN (step 609). The standard HLR 73 responds to such a request with a signal which includes the IMSI corresponding to the MSISDN in the request (step 610). (This "request for routing information" signal was provided under the GSM standard as a means of obtaining routing information for data messages intended for a destination for which only the MSISDN number is known. However, it may be used for other purposes, such as that described above).

The telephone identity (IMSI), whether obtained directly from the card reader 23 or handset 31, or indirectly as just described, is passed to a network registration unit 55 which exchanges signals with the mobile switching centre 50 in the same way that a real cellular telephone would do. The mobile switching centre therefore informs the user's Home Location Register 73 that the mobile telephone is now registered with the network 5 (step 611). The Home Location Register 73 records that the mobile handset is now registered with host MSC 50 (step 612).

30 In order to inform the user of the new voice mail message, the interface unit 52 must now forward the data message to the user terminal 21 (step 712) either during the call or after it ends. However, data messages are not suitable for switching via the MSC 50 and PSTN 8, nor for handling by the on-board terminal 21

as it is only equipped for voice. Because the IMSI is recorded in the HLR 73 as being registered with the "Virtual" BSC, or interface unit, 52, any other data messages intended for the user will also be routed to the interface unit 52, and require forwarding to the user. As with the call alerting process described above, the message may be displayed using the in flight entertainment system 200.

To allow the use of the at seat display system 201 for data messages, not suitable for transmission over the PSTN and satellite system in their original form the interface unit 52 is provided with a data handling processor 53 for receiving data messages received over a packet data system 9 by way of the MSC 50 and intended for users currently associated with the interface unit 52. These messages include SMS messages sent from other callers, and SMS messages generated by the MSC 50 itself to alert the user that a message has been sent to the voice mail system. The format of such a message is shown in Figure 9, and the process of sending and receiving it is shown in Figure 10.

The original message 900 basically consists of a data payload 901 and an address 902, which is the IMSI of the destination mobile telephone (figure 9a).

When the interface unit 53 receives such a data message (step 990) it retrieves from the data acquisition unit 54 the data network address of the at-seat entertainment terminal 200 corresponding to the user's cellular identity which was originally provided to the data acquisition unit 54 when the user carried out the registration procedure (step 991). The interface unit 53 next generates a data call to that address (step 992), in a form suitable for transmission by the MSC 50 (step 993) over the packet data network 9 to the aircraft 2, with an address header corresponding to the data network address of the user's at-seat terminal 200. This data call may be a short message to indicate that a message is awaiting delivery, and displaying on the screen 201 an invitation to the user to dial a special code on his handset 25 to accept the message (step 994), and any charge associated with it. This acceptance is transmitted back, by way of the MSC 50 to the interface unit 53 (step 995). (These steps 992 – 995 may be omitted if it is not required for users to acknowledge acceptance before receiving a data message).

The interface unit 53 then replaces the address header (the IMSI) 902 in the original data message with a code 912 identifying the terminal 200 and encapsulates the message in a form suitable for transmission over the packet data network 9 to

the aircraft (step 996), with an address header 910 to send it to the data network interface server 28 serving the onboard entertainment system 200. It can thus be transmitted to the data interface 28 over the packet data network 9 (step 997), effectively as a packet with an address header 910 and a payload made up of the at-seat terminal number 912 and true payload 901 (Figure 9b).

On receipt of the data message, the data interface 28 extracts the data message payload 901, 912, (Figure 9c) (step 998) and identifies the individual at-seat terminal 200 identified by the address 912. It can then cause display of the data message payload 901 on the screen 201 of the appropriate terminal (step 999).

If password protection is required, for example to ensure that the user is present when the message is displayed, the payload 901, 912 can also include a password code 913, which causes the interface server 28 to withhold the remainder of the payload until a predetermined sequence of keystrokes has been entered by the user in the terminal 200.

As the termination is itself mobile, being on board an aircraft, call routing to that termination may require revision from time to time. For example, the "Inmarsat" satellite system comprises several geostationary satellites, which each provide cover for part of the earth's surface. These areas of coverage overlap to a large extent, but nevertheless on a long flight the aircraft may pass out of the area covered by one satellite into that served by another. This causes a small but significant change in the network address of any satellite terminal on board the aircraft. The aircraft location register 41 monitors the identity of all aircraft currently being handled by each ground station 4. When an aircraft location is updated, the call diversion instruction unit 56 responds by transmitting a new call diversion instruction to the VLR 51 so that any further incoming call attempts are diverted to the new network address of the terminal. Note that the diversion store 57 is not updated. Note also that this does not affect calls already in progress: there is usually sufficient overlap in coverage areas that handover from one satellite or base station to another can be arranged to take place when no call is in progress.

Figure 11 shows a process for intercepting calls when the onboard system 1 is switched off at times when its operation could interfere with conventional land-based cellular systems or with electronic control systems of the vehicle, to enforce "quiet" periods on board, or to allow transfer of the satellite link from one satellite to

another. The control to switch the system off may be performed manually or under the control of a sensor detecting interference from nearby radio base stations 74, or an operational condition of the vehicle, such as deployment of the aircraft undercarriage, low altitude, or "weight on wheels", communicated to the onboard system by means of a control data bus e.g. 22. When such a disconnection occurs (step 1501), a signal is generated in the onboard system 2 (step 1502) for transmission over the satellite link 6 to the ground station 4 (step 1503). This signal causes the satellite ground station to invoke a call failure mode for any call directed to the onboard system 2 of the specified vehicle (step 1504).

Any call now diverted by the MSC 50 to a number corresponding to a node on board the vehicle (step 1505) will then receive a "call failed" indication from the ground station (step 1506), without any signalling required over the satellite link 6. Such failed calls will be re-routed according to the user's own diversion instructions, stored by the host MSC 50 for use when the user's handset is busy (step 1507). Generally, such instructions will be to divert the call to a voicemail system in the user's home network. In addition, the host MSC 50 will record the existence, and possibly the origin (Calling line identity – CLI) of any such call attempts (step 1508).

When the onboard system 2 is re-activated (step 1511) a further signal is transmitted by the onboard system (step 1512) for transmission over the satellite link 6 to the ground station 4 (step 1513). This signal causes the satellite ground station to revoke the call failure mode for calls directed to the onboard system 2 of the specified vehicle (step 1514). When a user 21 reconnects to the onboard system 2 (step 1515) the onboard system transmits a signal to the host MSC 50 (step 1516) which causes the host MSC 50 to retrieve the call attempt record previously stored for that user (step 1518). If one or more such call attempts have been made, the MSC returns a message to the user terminal 21 (step 1519), prompting the user to retrieve his messages from the voicemail system should he so wish.

Generally, the detection of the same IMSI from two sources would cause the HLR to disconnect both callers as a fraud prevention measure. Since the present system causes the generation of an IMSI from the interface unit 52, instead of directly from the mobile telephone to which that IMSI relates, the user's mobile telephone should be switched off, or connected to an onboard interface device 311 which disconnects the radio circuits, to prevent the network detecting the IMSI in

two places, which would disrupt the call routing processes in the HLR 73 and elsewhere.. If the user is on board an aircraft, he should not be using his mobile handset in the conventional manner, and so there should be no problem. However, if the user, having left the aircraft, switches on his telephone 75 before the network 5 has reported a loss of the mobile unit from its own network, the mobile unit may be perceived by the HLR 73 as being registered with two networks at once. To avoid this possibility, a disconnection procedure is followed as described with reference to Figure 8.

As already discussed, a disconnection signal may be transmitted from the on board system 28 to the card management system 42 and thus to the host network's interface unit 52 (step 801). The disconnection signal may be activated by a special code entered by the user 21, or it may be generated automatically by data collected from the aircraft's data bus 22, indicative of the imminent end of the flight. Note that this disconnection signal merely controls the interface 52 – it has no effect on calls in progress, which is routed from the MSC 5 by way of the PSTN 8.

The disconnect instruction is received by the interface unit 52 (step 802) and causes the call diversion instruction unit 56 to retrieve the call diversion data stored in the store 57 (step 803) and generate a call diversion instruction restoring the original settings to the VLR 51 (step 804). This ensures no further calls are routed to the onboard terminal 21.

The interface unit 52 next causes the network registration unit 55 in the interface unit 5 to instruct the MSC 50 that the user is no longer connected to the network 5 (step 805). This allows the mobile unit to register with another network 7 in the normal way. Call attempts to the user number will continue to be routed by the Home HLR 73 to the MSC 50 with which the mobile unit was most recently registered, but as the MSC cannot now find the mobile unit, any such incoming call will return a "not found" signal to the home MSC 70 which will divert the call according to any diversion instructions set up, or fail the call. Alternatively, the host MSC 50 may handle the diversion itself if the mobile unit is "not found", using the original diversion instructions now in the VLR 51, having been retrieved from the store 57 (step 804 above).

Having left the aircraft, the user may switch on his mobile telephone 75, which will register with the local network (e.g.7) and will retrieve the original divert

information from the HLR 73 (note that in general the HLR 73 will not be in the same network), and will cause all data relating to the user to be deleted from the VLR 51 in the "host" network 5.

CLAIMS

1. Apparatus for enabling a first termination point of a first telecommunications system to initiate call diversion instructions in the switching system of a second telecommunications system such that calls initially directed to a telephone apparatus
5 usable with the second telecommunications system are diverted to a selected termination point in the first telecommunications system, the apparatus comprising:
means in the first telecommunications system for identifying the telephone apparatus from which calls are to be diverted and the selected termination point to which calls are to be diverted,
10 and an interface means between the first telecommunications system and the switching system of the second telecommunications system, the interface means comprising:
means to indicate to the switching system that the telephone apparatus is in a specified operating condition, irrespective of the true operating
15 condition of the telephone apparatus,
and means to generate an instruction to the switching system to divert calls, intended for the telephone apparatus, to the said selected termination point of the first telecommunications system when the telephone apparatus is indicated as being in the said predetermined operating condition.
20
2. Apparatus according to claim 1, wherein the first termination point is provided with reading apparatus for reading an information carrier encoded with the user's identity
- 25 3 Apparatus according to claim 2, wherein the reading apparatus is arranged to co-operate with the part of a cellular telephone containing the user identity
4. Apparatus according to any preceding claim, wherein the first termination point is associated with an audio or visual display apparatus, and is provided with means
30 for detecting a ringing tone delivered to the first termination point, and means for generating a signal for transmission to the display apparatus in response to said ringing tone, in order to cause the display apparatus to display a call alert indication.

9. Apparatus according to claim 1, 2 3, 4, 5, 6, 7, or 8, wherein the interface has means to store the addresses of termination points in the first system, means to record changes to the said addresses transmitted to it from the first system, and

15. Apparatus according to claim 14, further comprising means for transmitting a
30 signal to the first termination point indicative of a call being sent to the selected
termination point.

16. Method of initiating, from a first termination point of a first telecommunications system, call diversion instructions in the switching system of a second telecommunications system such that calls initially directed to a telephone apparatus usable with the second telecommunications system are diverted to a
5 selected termination point in the first telecommunications system, the method comprising the steps of;

in the first telecommunications system, identifying the telephone apparatus from which calls are to be diverted and the selected termination point to which calls are to be diverted,

10 indicating to the switching system of the second telecommunications system that the telephone apparatus is in a specified operating condition, irrespective of the true operating condition of the telephone apparatus,

and generating an instruction to the switching system to divert calls, intended for the telephone apparatus, to the said selected termination point of the first
15 telecommunications system when the telephone apparatus is indicated as being in the said predetermined operating condition.

17. Method according to claim 16, wherein the first termination point in the first network reads an information carrier encoded with the user's identity

20

18. Method according to claim 16, wherein the reading apparatus co-operates with the part of a cellular telephone containing the user identity

19. Method according to any of claims 16, 17 or 18, wherein when ringing tone is
25 delivered to the selected termination point, a signal is transmitted to an audio or visual display apparatus associated with the selected termination point, to cause the display apparatus to display a call alert indication.

20. A method of interconnecting a first telecommunications system with a second
30 telecommunications system such that calls directed to telephone apparatus configured for use with the second telecommunications system may be diverted to a selected termination point in the first telecommunications system, comprising the steps of:

generating an instruction to the switching system of the second telecommunications system to divert calls directed to the telephone apparatus to the said selected termination point of the first telecommunications system when the telephone apparatus is indicated as being in the said predetermined operating condition

- 5 receiving data identifying a user and a selected termination point in the first network, indicating to the switching system of the second telecommunication system that a telephone terminal associated with the user is in a specified operating condition, irrespective of the true operating condition of the telephone terminal, generating an instruction to the switching system of the second telecommunications
10 system to divert calls directed to the telephone user to the said selected termination point of the first telecommunications system when the telephone apparatus is indicated as being in the said predetermined operating condition.

21. Method according to claim 16, 17, 18, 19, or 20 comprising the step of
15 according any diversion settings existing for the telephone apparatus prior to the diversion to the second network being set up.

22. Method according to claim 21, comprising the steps of retrieving the said settings when the user disconnects from the first telecommunications system, and
20 reinstating them in the switching system of the second telecommunications system.

23. Method according to claim 16, 17, 18, 19, 20, 21, or 22, wherein, if the second telecommunications system detects a second call attempt when a first call attempt has been diverted to the said termination point, said second call attempt is
25 diverted to a predetermined destination, and a signal is transmitted to the said selected termination point indicative of the second attempt.

24. Method according to claim 16, 17, 18, 19, 20, 21, 22, or 23, comprising the steps of storing the addresses of termination points of the first system, recording
30 changes to the said addresses, and modifying the diversion instructions in the interface unit switching system when such a change takes place.

25. A method of interconnecting a first telecommunications system with a second telecommunications system to allow calls initially directed to a telephone apparatus usable with the second telecommunications system to be diverted to a selected termination point in the first telecommunications system, comprising the
5 steps of;

receiving, from a first termination point in the first telecommunications system, identification information relating to the telephone apparatus,
receiving associated identification information from the first termination point,
transmitting the identification information to the second network,
10 receiving authentication data from the second network, and
connecting calls to or from the selected termination point in response to said authentication data.

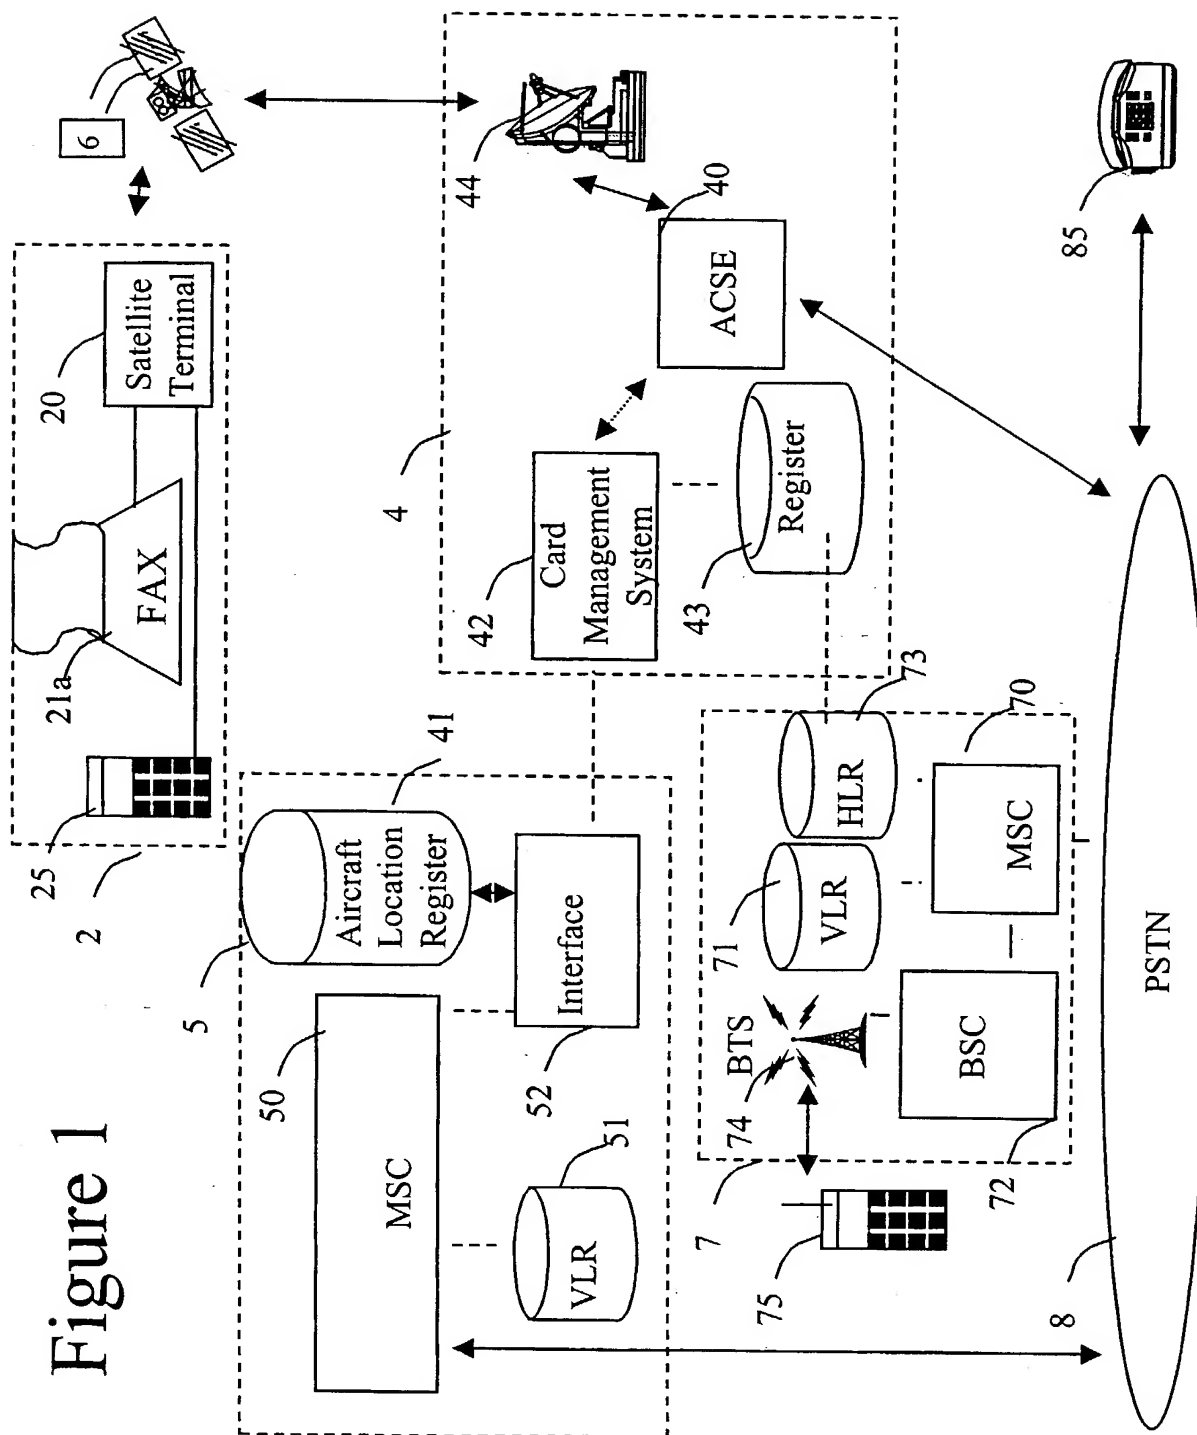

26. Method according to any of claims 16 to 25 wherein the first
15 telecommunications system is a satellite telephone system.

27. Method according to any of claims 16 to 26 wherein the second telecommunications system is a cellular radio system and the telephone apparatus is the part of a cellular telephone containing the user identity
20

28. Method according to claim 27 wherein the interface means appears to the switching system as one of the base stations of the cellular radio system, and through which the cellular telephone is currently operating.

25 29. Method according to any of claims 16 to 28, wherein the selected termination point is not the first termination point.

30. Method according to claim 29, wherein when a call is sent to the selected termination point a signal is also transmitted to the first termination point indicative
30 of the call being sent to the selected termination point.

[Continued on next page]

(54) Title: CALL DIVERSION SYSTEM

(57) Abstract: An interface (52) is provided between a satellite telephone system (4) and a cellular telephone system (5) for allowing calls to a user's cellular telephone to be diverted to a satellite telephone (25) when the user is unable to use his cellular telephone, for example when on board an aeroplane (2) fitted with a satellite telephone system (20). The user inserts a card (which may be the SIM of his mobile phone, or a card compatible with existing satellite telephone equipment) into a suitable reader in the satellite telephone (20), which causes the satellite ground station's card verification system (42) to connect to a host cellular network (50). The host cellular network has an interface unit (52) which emulates the operation of a normal base station, so that the host cellular system (50) acts as if the mobile user's terminal is roaming on the host network, but is currently "busy". The interface (52) also resets the user's existing call diversion instructions so that when the host cellular system (5) receives a busy tone from the base station emulator (52), it routes calls to the directory number of the terminal (20).

DECLARATION AND POWER OF ATTORNEY FOR UTILITY OR DESIGN PATENT APPLICATION (37 CFR 1.63) <input type="checkbox"/> Declaration Submitted with Initial Filing <input checked="" type="checkbox"/> Declaration Submitted After Initial Filing (surcharge (37 CFR 1.16(e)) required)	Attorney Docket Number	11696.0052
	First Named Inventor	ANDREW W. ALLAWAY
	COMPLETE IF KNOWN	
	Application Number	10/088,030
	Filing Date	March 14, 2002

	Examiner Name	

As a below named inventor, I hereby declare that:

My residence, mailing address, and citizenship are as stated below next to my name.

I believe I am an original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

CALL DIVERSION SYSTEM
(Title of the Invention)

the specification of which

☐ is attached hereto
OR

☒ was filed on (MM/DD/YYYY) 03/14/2002 as United States Application Number 10/088,030 or PCT International Application Number and was amended on (MM/DD/YYYY) 03/14/2002 (if applicable).

I hereby state that I have reviewed and understand the contents of the above-identified specification; including the claims, as amended by any amendment specifically referred to above.

POWER OF ATTORNEY: I hereby appoint the practitioner(s) named below to prosecute the application identified above, and to transact all business in the United States Patent and Trademark Office connected therewith:
